Agenda

- What is openMP?
- Starting parallel region
- Data Scopes
- Work sharing
- Dependencies and Reductions
- Synchronization
- Scheduling
- OpenMP tasks
Short course home page:
https://hprc.tamu.edu/training/intro_openmp.html

Setting up OpenMP sample codes:

Type: /scratch/training/OpenMP/setup.sh
(in terra, ada, or curie shell)
All modern computers have multiple processing cores (4 to 8 on average desktop). On terra, each NODE has 28 cores (two 14 core cpus) per node and at least 64GB of SHARED memory

(NOTE: ada has 20 cores per node and curie has 16)
Basic Computer Architecture

All modern computers have multiple processing cores (4 to 8 on average desktop). On terra, each NODE has 28 cores (two 14 core cpus) per node and at least 64GB of **SHARED** memory

(NOTE: ada has 20 cores per node and curie has 16)
What is OpenMP?

Defacto standard API for writing *shared memory* parallel applications in C, C++, and Fortran

OpenMP API consists of:

- Compiler pragmas/directives
- Runtime subroutines/functions
- Environment variables

In a nutshell: using OpenMP, you can make a serial program run in parallel by annotating parts of the code that you want to run in parallel

**C/C++ pragma format:**

```c
#pragma omp directive [clauses]
{
  
}
```

**Not case sensitive**

**New line required**

**fortran directive format:**

```fortran
!$OMP DIRECTIVE [clauses]
  
!$OMP END DIRECTIVE
```

**Not case sensitive**

**New line required**
Starting Parallel Region

This will start an OpenMP region. The OpenMP runtime will create a team of **threads**. The code inside the parallel block will be executed concurrently by all threads.
HelloWorld

Exercise:

1) Create OpenMP version of HelloWorld (either C/C++ or Fortran)
   a) Create parallel region
   b) Every thread prints Hello World
   c) Close the parallel region
2) Compile the program (you can use GNU or Intel compiler)
3) Execute the program
#include <iostream>

int main() {
    #pragma omp parallel
    {
        std::cout << "Hello World\n";
    }
    return 0;
}

Need to include flag to tell the compiler to process the OpenMP pragmas/directives

intel: icpc -qopenmp -o hi.x hello.cpp
gnu:  g++ -fopenmp -o hi.x hello.cpp

intel: ifort -qopenmp -o hi.x hello.f90
gnu:  gfortran -fopenmp -o hi.x hello.f90

Compile the program, and run again
Hello World

#include <iostream>

int main() {
    #pragma omp parallel
    {
        std::cout << "Hello World\n";
    }
    return 0;
}

Need to include flag to tell the compiler to process the OpenMP pragmas/directives

intel: icpc -qopenmp -o hi.x hello.cpp
gnu:  g++ -fopenmp -o hi.x hello.cpp

RUNNING

export OMP_NUM_THREADS=4
./hi.x

Run the program again
(I promise, it will work now)
Fork/Join

#include <iostream>
#include <omp.h>

using std;

int main() {
    #pragma omp parallel
    {
        cout << "Hello world\n";
    }
    return 0;
}

Runtime starts additional threads at start of openmp region

#include <iostream>
#include <omp.h>

using std;

int main() {
    #pragma omp parallel
    {
        cout << "Hello World";
    }
    return 0;
}
(OpenMP) THREAD: Independent sequence of code, with a single entry and a single exit

CORE: Physical processing unit that receives instructions and performs calculations, or actions, based on those instructions.

- OpenMP threads are mapped onto physical cores
- Possible to map more than 1 thread onto a core
- In practice best to have one-to-one mapping.
Getting Thread info

- Runtime function: `omp_get_thread_num()`

```c
id = omp_get_thread_num(); // 0
#pragma omp parallel
{
    id = omp_get_thread_num(); // <thread id in region>
}
```

- Runtime function: `omp_get_num_threads()`

```c
tot = omp_get_num_threads(); // 1
#pragma omp parallel
{
    tot = omp_get_num_threads(); // <total #threads in region>
}
```
Setting the number of Threads

- Environmental variable: `OMP_NUM_THREADS`
  
  ```
  export OMP_NUM_THREADS=4
  ./a.out
  ```

- Runtime function: `omp_set_num_threads(n)`
  
  ```
  omp_set_num_threads(4);
  #pragma omp parallel
  :
  ```

- OMP PARALLEL clause: `num_threads(n)`
  
  ```
  #pragma omp parallel num_threads(4)
  ```
Hello Threads

Exercise:

1) Create OpenMP HelloThreads program that does the following:
   a) Create parallel region
   b) Every thread prints its thread id and the total number of threads
   c) Close the parallel region
2) Compile the program (you can use GNU or Intel compiler)
3) Execute the program

HINT: since you will be using OpenMP library functions you include:

C/C++ : `#include “omp.h”`
Fortran : `use omp_lib`
#pragma omp parallel
{
    tot = omp_get_num_threads();
    id = omp_get_thread_num();
}

Remember: memory is (conceptually) shared by all threads
#pragma omp parallel 
{
    tot = omp_get_num_threads();
    id = omp_get_thread_num();
}

Remember: memory is (conceptually) shared by all threads

All threads try to access the same variable (possibly at the same time). This can lead to a race condition. Different runs of same program might give different results because of these race conditions.
Index variables (Fortran, C/C++) and variables declared inside parallel region (C/C++) are considered private by default.

Data scope clauses: \texttt{private(list)}

\begin{verbatim}
#pragma omp parallel private(a,c) 
{
    
} 
#endif

// Data Scope Clauses
#pragma omp parallel private(a,c)
{
    
}
#endif

- Every thread will have its own \texttt{"private"} copy of variables in list
- No other thread has access to this \texttt{"private"} copy
- Private variables are NOT initialized with value before region started (use \texttt{firstprivate} instead)
- Private variables are NOT accessible after enclosing region finishes
Data Scope Clauses

Data scope clauses: `shared(list)`

```plaintext
#pragma omp parallel shared(a,c)
{
}

!$OMP PARALLEL SHARED(a,c)
{
}

By default most variables in work sharing constructs are considered shared in OpenMP. Exceptions include index variables (Fortran, C/C++) and variables declared inside parallel region (C/C++).
Other Data Scope Clauses

Data scope clauses: `firstprivate(list)`

- Every thread will have its own "private" copy of variables in list.
- No other thread has access to this "private" copy.
- `firstprivate` variables are initialized to value before region started.
- `firstprivate` variables are NOT accessible after end of enclosing region.

Data scope clause: `default(shared | private | firstprivate | lastprivate)`

- Set default data scoping rule.
- If not set, default depends on the pragma/directive (e.g. Shared for "for" pragma).
Hello Threads (take 2)

Exercise:

1) Create OpenMP HelloThreads program that does the following:
   a) Create parallel region
   b) Every thread prints its own thread id and the total number of threads
   c) Close the parallel region

2) Compile the program (you can use GNU or Intel compiler)
3) Execute the program
```c
#pragma omp parallel
{
    tot = omp_get_num_threads();
    id = omp_get_thread_num();
}
```
OpenMP creates separate data stack for every worker thread to store private variables (master thread uses regular stack).

- Size of these stacks is not defined by OpenMP standards.
- Behavior of program undefined when stack space exceeded.
  - Although most compilers/RT will throw seg fault.
  - To set stack size use environment var OMP_STACKSIZE:
    - export OMP_STACKSIZE=512M
    - export OMP_STACKSIZE=1G
  - To make sure master thread has large enough stack space use ulimit -s command (unix/linux).

Let's create a demo program where the threads fill up the stack space.
Work Sharing Directives

Work sharing pragma (C/C++): \texttt{#pragma omp for} \texttt{[clauses]}

\begin{itemize}
  \item \begin{verbatim}
  #pragma omp parallel
  #pragma omp for
  for (int i=1; i<N; ++i)
  A(i) = A(i) + B;
  \end{verbatim}
  \end{itemize}

\begin{itemize}
  \item OR \begin{verbatim}
  #pragma omp parallel for
  for (int i=1; i<N; ++i)
  A(i) = A(i) + B;
  \end{verbatim}
  \end{itemize}

- for command must immediately follow “\texttt{#pragma omp for}”
- Newline required after “\texttt{#pragma omp for}”
- Originally iteration variable could only be signed/unsigned integer variable.
Work Sharing Directives

Work sharing directive (Fortran):  !$OMP DO \[clauses\]

- DO command must immediately follow “!$OMP DO” directive
- Loop iteration variable is “private” by default
- If “end do” directive omitted it is assumed at end of loop
- Not case sensitive
Work Sharing

#pragma omp parallel for
for (int i=1; i<1000; ++i)
    A(i) = A(i) + B;

for (int i=1; i<250; ++i)
    A(i) = A(i) + B;

for (int i=251; i<500; ++i)
    A(i) = A(i) + B;

for (int i=501; i<750; ++i)
    A(i) = A(i) + B;

for (int i=751; i<1000; ++i)
    A(i) = A(i) + B;
Work Sharing Directives

Random access iterators:

```cpp
vector<int> vec(10);
vector<int>::iterator it = vec.begin();
#pragma omp parallel for
for (; it != vec.end(); ++it) {
    // do something with *it
}
```

Pointer type:

```cpp
int N = 1000000;
int arr[N];
#pragma omp parallel for
for (int* t = arr; t < arr + N; ++t) {
    // do something with *t
}
```
Matrix multiplication

Exercise:

1) Create program that computes simple matrix vector multiplication:
   a) Use the OpenMP work sharing construct
   b) Create as function that takes as arguments matrix and vector
   c) Add timing to see the running time.

2) Compile and run the program

3) Try it with various number of threads

4) Vary the input size and see how it affects run time
Case Study:
Assume the following dummy program:

```c
A=int[N]; // set all elements to -1
for (int i=0 ; i<N ; ++i) A[i] = i;
```

We want to run this in parallel. Normally we would use the OpenMP worksharing directive. Let’s do it without and partition the loop manually

1) Start a parallel region.
2) Every thread will compute its offsets
3) Every thread will process part of the loop.
TIP: ORPHANED PRAGMAS

An OpenMP pragma that appears independently from another enclosing pragma is called an **orphaned** pragma. It exists outside of another pragma static extent.

```c
int main() {
    #pragma omp parallel
    foo()
    return 0;
}

void foo() {
    #pragma omp for
    for (int i=0; i<N; i++) {....}
}
```

*Note: OpenMP directives (pragmas) should be in the dynamic extent of a parallel section directive (pragma).*
Data Dependencies

Can all loops can be parallelized?

```
for (i=1 ; i<N ; ++i)
    A[i] = A[i-1] + 1
end
```

```
#pragma omp parallel for
for (i=1 ; i<N ; ++i)
    A[i] = A[i-1] + 1
end
```

Is the result guaranteed to be correct if you run this loop in parallel?
Can all loops can be parallelized?

```
for (i=1 ; i<N ; ++i)
    A[i] = A[i-1] + 1
end
```

#pragma omp parallel for
```
for (i=1 ; i<N ; ++i)
    A[i] = A[i-1] + 1
end
```

Unroll the loop (partly):

- **iteration i=1:**  
  - $A[1]$ used here, defined in previous iteration

- **iteration i=2:**  
  - $A[2]$ used here, defined in previous iteration

- **iteration i=3:**  
A reduction variable is a special variable that is **updated** during every iteration of a loop and there are no other definitions or uses of that variable. Update is always of the form “a = a op b”

Can we run this in parallel?

```c
for (int i=0;i<10;++i)
    sum=sum+a[i];
```

```c
#pragma omp parallel for
for (int i=0;i<10;++i)
    sum=sum+a[i];
```
**Reductions**

A reduction variable is a special variable that is **updated** during every iteration of a loop and there are no other definitions or uses of that variable. Update is always of the form “\( a = a \text{ op } b \)”

Data scope clause: **REDUCTION(op:list)**

- Only certain kind of operators allowed
  - ✔️ +, -, *, max, min,
  - ✔️ &, |, ^, &&, || (C/ C++)
  - ✔️ .and., .or., .eqv., .neqv., iand, ior, ieor (Fortran)
- OpenMP 4.0 allows for user defined reductions

```
for (int i=0; i<10; ++i)
  sum=sum+a[i];
```

```
#pragma omp parallel for reduction(+:sum)
for (int i=0; i<10; ++i)
  sum=sum+a[i];
```
Dot product (take 1)

Exercise:

1) Create program that takes 2 vectors (arrays) and computes:
   a) The dot product of the vectors
   b) the largest element of the two vectors
2) Add timing to compute the run time
3) Compile and run the program
4) Try it with various number of threads
User Defined Reductions

New in OpenMP 4.0

```
#pragma omp declare reduction (name : type list : combiner) \ninitializer(initializer-expression)

!$ omp declare reduction (name : type list : combiner) \ninitializer(initializer-expression)
```

Example: UDR that computes sum (mimics + operator)

```
#pragma omp declare reduction (mysum : int : omp_out = omp_out + omp_in) \ninitializer(omp_priv = 0)
```

Fixed variable names to represent in and out of reduction

Fixed variable name to represent initializer
User Defined Reductions

Case Study:
suppose we have a vector of random points (with x and y coordinates). We want to find the point with the longest distance \( d = \sqrt{x^2+y^2} \)

1) Create a C++ class with
   a) Two members: x and y coordinate
   b) Member function that computes the distance
2) Create User Defined Reduction that takes pair of points and returns one with longest distance
3) Create OpenMP loop with reduction clause that computes the point with longest distance.
4) Compile and run with various number of threads.
Work Sharing Directives

```c
#pragma omp sections !$OMP SECTIONS

#pragma omp parallel
{
  #pragma omp sections
  {
    #pragma omp section
    process(A1,A2)
    #pragma omp section
    process(B1,B2)
  }
}
```

- In an OpenMP sessions block, all "sections" will be executed concurrently
- Each section will be processed by a separate thread
- How is this different from `#pragma omp for`

```c
#pragma omp single !$OMP SINGLE

#pragma omp parallel
{
  #pragma omp single
  {
    std::cout << "thread" << omp_get_thread_num() << " reached here first\n";
  }
}
```

- One thread (not necessarily master) executes the block
- Other threads will wait
- Useful for thread-unsafe code
- Useful for I/O operations
NOWAIT Clause

Worksharing constructs have an implicit barrier at the end of their worksharing region. To omit this barrier:

```
#pragma omp for nowait
    
!$OMP DO
    
    !$OMP END DO NOWAIT
```

- At end of work sharing constructs threads will **not** wait
- There is always barrier at end of parallel region

**NOTE:** In example above the nowait clause is used with a for/do work sharing construct. It also works with the other worksharing construct: sections and single

demo nowait as part of single construct
OpenMP programs use shared variables to communicate. Need to make sure these variables are not accessed at the same time by different threads to avoid race conditions.
Synchronization Directive

#pragma omp critical (!$OMP CRITICAL)

- **ALL** threads will execute the code inside the block
- Execution of the block is serialized, only one thread at a time will execute the block
- Threads will wait at start of block when another thread already inside the block

```c
int tot=0; int id=0;
#pragma omp parallel
{
#pragma omp critical
{
    id = omp_get_thread_num(); tot=tot+id;
    std::cout << "id " << id << " tot:  " << tot << "\n";
}
// do some other stuff
}
```

NOTE: If block consists of only a single assignment can use `#pragma omp atomic` instead
Thread 3 reaches critical block first, starts executing

Thread 1 reaches critical block. Thread 3 still executing, so has to wait

Thread 3 finished, will continue

Thread 1 finished, will continue

Thread 1 reaches critical block. Thread 3 still executing, so has to wait

Thread 0 finished, will continue

Thread 1 finished, will continue

Thread 0 finished, will continue

Thread 2

#pragma omp critical
{
    // some code
}

Thread 3

#pragma omp critical
{
    // some code
}

Thread 0

#pragma omp critical
{
    // some code
}

Thread 2

#pragma omp critical
{
    // some code
}
Dot product (take 2)

Exercise:

1) Create program that takes 2 vectors and computes:
   a) The dot product of the vectors
   b) the largest element of the two vectors
   c) This time use OpenMP atomic blocks
2) Add timing to compute the run time
3) Compile and run the program
4) Try it with various number of threads
Synchronization pragma

#pragma omp master (!$OMP MASTER)

- **ONLY** master threads will execute the code inside the block
- Other threads will skip executing the block
- Other threads will not wait at end of the block

#pragma omp barrier (!$OMP BARRIER)

- **ALL** threads will wait at the barrier.
- Only when all threads have reached the barrier, each thread can continue
- Already seen implicit barriers, e.g. at the end of "#pragma omp parallel", "#pragma omp for"
OpenMP provides another useful clause to decide at run time if a parallel region should actually be run in parallel (multiple threads) or just by the master thread:

```plaintext
IF (logical expr)
```

For example:

```
$!OMP PARALLEL IF(n > 100000)  \ (\text{fortran)}
#pragma omp parallel if (n>100000) \ (\text{C/C++})
```

This will only run the parallel region when \( n > 100000 \)
TIP: Printing OMP env vars

OpenMP 4.0 introduces a new environmental variable that instructs the runtime to print version number and all OpenMP environmental variables:

OMP_DISPLAY_ENV=VERBOSE

To only print the OpenMP version number, you can use:

OMP_DISPLAY_ENV=TRUE
Although the OpenMP standard does not specify how a loop should be partitioned most compilers split the loop in \( N/p \) (\( N \) #iterations, \( p \) #threads) chunks by default.
Scheduling Clauses

**SCHEDULE (STATIC,10)** //loop with 1000 iterations, 4 threads

```c
!$OMP PARALLEL DO SCHEDULE (STATIC,10)
DO i=1,1000
 : 
ENDDO
!$OMP END PARALLEL DO

#pragma omp parallel for schedule(static,10)
for (int i=0;i<1000;++i) {
 : 
}
```

Texas A&M University     High Performance Research Computing  –  https://hprc.tamu.edu
With static scheduling the number of iterations is evenly distributed among all OpenMP threads. This is not always the best way to partition. Why?

How can this happen?
Scheduling Clauses

With static scheduling the number of iterations is evenly distributed among all OpenMP threads. This is not always the best way to partition. Why?

![Diagram showing iterations](image)

This is called load imbalance. In this case, threads 2, 3, and 4 will be waiting very long for thread 1 to finish.

How can this happen?
Loop iterations are divided into pieces of size chunk. When a thread finishes one chunk, it is dynamically assigned another.

**NOTE:** there is a significant overhead involved compared to static scheduling. **WHY?**
Scheduling Clauses

SCHEDULE (GUIDED,10) //loop with 1000 iterations, 4 threads

!$OMP PARALLEL DO SCHEDULE (GUIDED,10)
DO i=1,1000
  :
ENDDO
!$OMP END PARALLEL DO

Similar to DYNAMIC schedule except that chunk size is relative to number of iterations left.

NOTE: there is a significant overhead involved compared to static scheduling. WHY?
Nested Parallelism

OpenMP allows parallel regions inside other parallel regions

```c
#pragma omp parallel for
for (int i=0; i<N;++i) {
    #pragma omp parallel for
    for (j=0;j<M;++j)
}
```

- To enable nested parallelism:
  - env var: OMP_NESTED=1
  - lib function: omp_set_nested(1)

- To specify number of threads:
  - omp_set_num_threads()
  - OMP_NUM_THREADS=4,2

NOTE: using nested parallelism does introduce extra overhead and might over-subscribe of threads
OpenMP Tasks

Especially useful for unbounded loops, Irregular algorithms, Tree/lists, Recursive algorithms, Producer/Consumer type problems.

- Each task is independent unit of work
- When a thread encounters a task construct, thread decides to execute it itself or put in task pool
- Available threads will execute tasks
- Tasks consist of:
  - Code to execute
  - Data environment

New in OpenMP 3.0

Available threads retrieve tasks from the pool and execute them
OpenMP Tasks

Creating tasks

`#pragma omp task`

- Defines/creates new task
- Task will be added to task pool
- Idle thread will get tasks from pool and executes it
- **Has to be in parallel region**

Synchronization

`#pragma omp taskwait`

- Acts like a barrier
- Thread wait until all child tasks have finished

Default Data Scope Rules

```c
int b, c;
#pragma omp parallel private (b)
{
    int d;
    #pragma omp task
    {
        int e;  // firstprivate
        b, d;  // firstprivate
        c;     // shared
        e;     // private
    }
}
```
Analysis of OpenMP Tasks

Start a parallel region

Add a single construct (why?)

Add a nowait clause (why?)

Create task

Wait until all child tasks have finished

What will the code print out, and in what order?

```c
#pragma omp parallel
{
    #pragma omp single nowait
    {
        #pragma omp task
        cout << "Thread " << id << " executing task 1\n";
        #pragma omp task
        cout << "Thread " << id << " executing task 2\n";
        #pragma omp taskwait
        printf("Finished with tasks\n");
    }
    int id = omp_get_thread_num();
    printf(" Thread %d says hello\n",id);
}
```
Dot product (take 3)

Exercise:

1) Create program that takes 2 vectors and computes:
   a) The dot product of the vectors
   b) the largest element of the two vectors
   c) This time, use OpenMP tasks
2) Add timing to compute the run time
3) Compile and run the program
4) Try it with various number of threads
The Intel Math Kernel Library (MKL) has very specialized and optimized versions of many math functions (e.g. blas, lapack). Many of these have been parallelized using OpenMP.

- MKL_NUM_THREADS
- OMP_NUM_THREADS
